

DATA RECEPTION/PLAYBACK METHOD,  
DATA RECEPTION/PLAYBACK APPARATUS,

DATA TRANSMISSION METHOD, AND DATA TRANSMISSION APPARATUS

FIELD OF THE INVENTION

The present invention relates to methods and apparatuses for transmitting, receiving, and playing audio data or video data (moving pictures, still pictures, graphics, etc.) through a network.

BACKGROUND OF THE INVENTION

In recent years, the Internet has attracted attention as means for exchanging information. As devices connectable to the Internet, such as personal computers, mobile terminals, handy phones and the like, are increasing, the Internet has come into general use. The WWW (World Wide Web) is the most popular system for providing information through the Internet, and the WWW employs the HTTP (Hyper Text Transfer Protocol) as a data transmission protocol.

Figure 17 is a diagram illustrating the flow of messages between a data transmission apparatus (HTTP server) and a data reception/playback apparatus (HTTP client) using the HTTP.

Initially, the data reception/playback apparatus 1701 conducts HTTP connection to the transmission apparatus 1702, and transmits a request for data transmission 1703. The transmission request 1703 is given an identifier corresponding to data (hereinafter referred to as data identifier 1704), which is

called an URI (Universal Resource Identifier), whereby the data reception/playback apparatus 1701 can request the transmission apparatus 1702 to transmit desired data. The transmission apparatus 1702 analyzes the transmission request 1703, stores the data corresponding to the data identifier in a transmission response 1705, and transmits it to the data reception/playback apparatus 1701. The data reception/playback apparatus 1701 receives the transmission response 1705. Through the above-mentioned procedure, the data reception/playback apparatus 1701 can take desired data from the transmission apparatus 1702.

Conventionally, data of texts, still pictures and the like have mainly been transmitted through the Internet. However, with enlargement of network band and advance of audio/video compression technology in recent years, the Internet can be employed for information provision services using audio and video.

Hereinafter, a description will be given of the construction of a data reception/playback apparatus for receiving and playing stream data of audio and video, and the construction of a data transmission apparatus for transmitting stream data of audio and video to the data reception/playback apparatus, with reference to figures 18 and 19.

Figure 18 is a block diagram illustrating the construction of the data reception/playback apparatus 1701. The data reception/playback apparatus 1701 comprises a transmission request sending means 1803 for sending a transmission request

1804; a reception means 1806 for receiving a transmission response 1805 to the transmission request 1804, from the transmission apparatus 1702; a reception buffer 1808 for storing the data received by the reception means 1806; a playback means 1812 for playing the stream data stored in the reception buffer 1808; and a control means 1801 for controlling the respective means mentioned above.

The data reception/playback apparatus 1701 so constructed operates as follows.

The control means 1801 instructs the transmission request sending means 1803 to send a transmission request (instruction signal 1802). The transmission request sending means 1803 sends a transmission request 1804 to the transmission apparatus 1702, according to the instruction of the control means 1801. On receipt of the request 1804, the transmission apparatus 1702 sends a transmission response 1805 to the receiving/playback apparatus 1701. As the result, the receiving means 1806 receives the transmission response 1805.

The receiving means 1806 stores data 1807 of the transmission response 1805 in the reception buffer 1808. At this time, the receiving means 1806 sends a notice of reception 1809 to the control means 1801. On receipt of the notice of reception 1809, the control means 1801 instructs the playback means 1812 to play the data 1811 stored in the reception buffer 1808 (instruction signal 1810). The playback means 1812 plays the

data 1811 read from the reception buffer 1808, and outputs the played data as an output signal 1813.

Next, a description will be given of the transmission apparatus 1702. Figure 19 is a block diagram illustrating the construction of the transmission apparatus 1702. The transmission apparatus 1702 comprises a transmission request reception means 1902 for receiving and analyzing a transmission request 1901 from the reception/playback apparatus 1701; a file selection means 1904 for selecting a file corresponding to a data identifier (URI) included in the transmission request 1901, from a data storage means 1907 (in this description, a file is defined as stream data recorded in a specific format); a file reading means for reading data from the file according to an instruction of the file selection means 1904; and a transmission means 1909 for transmitting the data read by the file reading means 1906.

The transmission apparatus 1702 so constructed operates as follows. The transmission request reception means 1902 receives and analyzes the transmission request 1901. Then, the transmission request reception means 1902 extracts the data identifier 1903 from the transmission request 1901, and informs it to the file selection means 1904. The file selection means 1904 selects a file corresponding to the data identifier 1903 from the data storage means 1907, and informs the selected file 1905 to the file reading means 1906. The file reading means 1906 reads data of the selected file from the data storage means 1907.

The transmission means 1909 transmits the data 1908 read by the file reading means 1906 as a transmission response 1910.

As described above, the reception/playback apparatus 1701 plays the audio or video transmitted from the transmission apparatus 1702 through the network.

Further, figure 9 shows the case where plural stream data are simultaneously received and synchronously played by using the data reception/playback apparatus 1701 and the data transmission apparatus 1702. As shown in figure 9, the data reception/playback apparatus 1701 outputs a transmission request for plural stream data to the transmission apparatus 1702 by using plural HTTP connections, and receives the plural stream data simultaneously to play them synchronously.

However, since the HTTP is not a protocol designed for audio/video transmission, it cannot provide playback control functions useful in audio/video playback, such as playback from some midpoint in stream data, suspension of playback, change of playback speed, and the like.

Further, when a delay in data transmission occurs due to network congestion and thereby data transmission is halted at some midpoint in the stream data being received, data playback is halted because the conventional data reception/playback apparatus cannot perform data playback from the midpoint in the stream data, resulting in lack of real-time performance in data playback.

In order to solve the above-mentioned problems, there is a

move afoot to construct a protocol for audio and video only, aside from the HTTP. However, such protocol for audio and video only will be an unprecedented one and, therefore, much time and cost will be spent before it is widely available.

Further, according to the HTTP, the quantity of data to be transmitted is controlled according to network congestion. However, when performing synchronous playback of plural stream data while receiving them simultaneously, since the quantity of data to be transmitted should be controlled for each connection, the quantity of data per unit time will vary from connection to connection.

Hereinafter, this problem will be described more specifically with reference to figures 10 and 11.

Figure 10 is a graph illustrating an example of the quantity of data stored in the reception buffer of the data reception/playback apparatus (hereinafter referred to as "buffer quantity"). The abscissa shows the time, and the ordinate shows the buffer quantity. The data received by the reception means is successively input to the reception buffer, and the store data is successively taken out by the playback means. Figure 10 shows the case where two streams of data 1001 and 1002 are received and played simultaneously.

In figure 10, the quantity of received data gradually decreases due to network congestion or the like, and the data of the stream 1 (1001) runs out at time T1 (1003), whereby data

000221-8496269

09739648-22000

playback is halted. Since the stream data 1 cannot be played any more, playback is halted until sufficient data is stored in the reception buffer. In this state, however, synchronous playback of the stream data 1 and the stream data 2 cannot be performed, and therefore, playback of the stream data 2 (1002) is also halted, and it is resumed when sufficient stream data 1 is stored.

The result is shown in figure 11. It is assumed that the stream data 1 (1101) in the reception buffer runs out at time T1 (1103). At this time, playbacks of the stream data 1 and the stream data 2 (1002) are stopped simultaneously. However, since data reception is still continued in the connection of the stream data 2, the maximum buffer quantity is exceeded at time T2 (1104). As the result, synchronous playback of plural stream data while receiving them simultaneously cannot be achieved.

#### SUMMARY OF THE INVENTION

The present invention is made to solve the above-described problems, and it is an object of the present invention to provide a data reception/playback method, a data reception/playback apparatus, a data transmission method, and a data transmission apparatus, which are able to realize playback control functions useful in audio/video playback, such as playback from some midpoint in stream data, suspension of playback, and change of playback speed, when performing audio/video transmission using the HTTP, and avoid degradation of data quality and overflow of reception buffer even when transmission delay occurs due to

network congestion.

Other objects and advantages of the invention will become apparent from the detailed description that follows. The detailed description and specific embodiments described are provided only for illustration since various additions and modifications within the scope of the invention will be apparent to those of skill in the art from the detailed description.

According to a first aspect of the present invention, there is provided a data reception/playback method for receiving and playing stream data including at least one of audio and video. This method comprises the steps of: before receiving the stream data, requesting a transmitting end to transmit part or whole of a playback start position table including at least one position where data playback can be started from some midpoint in the stream data; receiving the playback start position table; selecting one playback start position from the received playback start position table; requesting the transmitting end to transmit the stream data from the selected playback start position; and receiving and playing the stream data which has been transmitted from the playback start position. In this method, a playback start position table containing playback start positions is received from the transmitting end in advance of data playback, a playback start position is selected from the table, and transmission of data from the selected playback start position is requested to the transmitting end. Therefore, data playback from

some midpoint in stream data is achieved.

According to a second aspect of the present invention, in the data reception/playback method of the first aspect, the playback start position table is stored in a file different from a file containing the stream data; transmission of the file containing the playback start position table is requested to the transmitting end before reception of the stream data; and the playback start position table is extracted from the received file containing the table.

According to a third aspect of the present invention, in the data reception/playback method of the first aspect, the playback start position table, the stream data, and information about the position of the playback start position table are stored in one file; transmission of the file is requested to the transmitting end; the information about the position of the playback start position table is extracted from the data of the file received; transmission of the file from the position indicated by the information about the position of the playback start position table is requested to the transmitting end; and the playback start position table is obtained from the received data.

According to a fourth aspect of the present invention, in the data reception/playback method of the first aspect, the playback start position table received at the time of data playback is stored, and the stored table is used for the next and later data playback.

According to a fifth aspect of the present invention, in the data reception/playback method of the first aspect, when playing the stream data from the head of the stream, the stream data is received and played without requesting transmission of the playback start position table; and when playing the stream data from some midpoint in the stream, transmission of the playback start position table is requested.

According to a sixth aspect of the present invention, in the data reception/playback method of the third aspect, the information about the position of the playback start position table is stored at the time of data playback, and this positional information is used for the next and later data playback.

According to a seventh aspect of the present invention, there is provided a data reception/playback apparatus for receiving and playing stream data including at least one of audio and video. This apparatus comprises: transmission request sending means for sending a transmission request to a transmission apparatus; reception means for receiving data transmitted from the transmission apparatus in response to the transmission request; playback start position selection means for selecting a playback start position from a playback start position table where at least one playback start position is stored; and playback means for playing the stream data. In this apparatus, the transmission request sending means requests the transmission apparatus to transmit the playback start position

[illegible]

According to an eighth aspect of the present invention, there is provided a data reception/playback method for receiving and playing stream data including at least one of audio and video. In this method, when data playback is to be halted temporarily, a request for transmission halt is made to the transmitting end by halting data reception from a lower communication protocol; and when data playback is to be restarted, a request for transmission restart is made to the transmitting end by restarting data reception from the lower communication protocol. In this method, since a lower communication protocol requests the transmitting end to halt data transmission by halting data reception from the lower communication protocol, temporary halt of data playback can

be achieved. Further, when restarting data playback, the lower communication protocol requests the transmitting end to transmit data by restarting data reception from the lower communication protocol.

According to a ninth aspect of the present invention, there is provided a data reception/playback method for receiving and playing stream data including at least one of audio and video. In this method, when receiving and playing plural stream data simultaneously by using plural connections which are individually controllable, if reception of stream data in a connection is delayed for a playback time, playback of all the stream data is halted, and a request for suspension of data transmission in the connections including stream data other than the stream data which is delayed in reception, is output to the transmitting end; and when the quantity of the stream data which is delayed in reception exceeds a predetermined value, playback of all the stream data is restarted, and a request for restart of data transmission in the suspended connections is output to the transmitting end. Therefore, it is possible to avoid degradation in quality of played data due to interruptions of data, and overflow of a reception buffer.

According to a tenth aspect of the present invention, there is provided a data reception/playback apparatus for receiving and playing stream data including at least one of audio and video. This apparatus comprises: transmission request sending means for

requesting a transmission apparatus to transmit plural stream data; reception means for receiving the stream data; reception buffer for storing the stream data; playback means for playing the stream data stored in the reception buffer; and reception buffer monitor means for monitoring the quantity of data stored in the reception buffer. In this apparatus, when the reception buffer monitor means detects that reception of stream data is delayed for a playback time, the playback means halts playback of all the stream data, and the transmission request sending means requests the transmission apparatus to suspend data transmission in connections including stream data other than the stream data which is delayed in reception. When the reception buffer monitor means detects that the quantity of the stream data which is delayed in reception exceeds a predetermined value, the playback means restarts playback of all the stream data, and the transmission request sending means requests the transmission apparatus to restart data transmission in the connection which is suspended. Therefore, it is possible to avoid degradation in quality of played data due to interruptions of data, and overflow of the reception buffer.

According to an eleventh aspect of the present invention, there is provided a data transmission method for transmitting stream data including at least one of audio and video, according to a playback speed specified by a receiving end. This method comprises the steps of: having a plurality of files containing

00022T 8436750

stream data of different playback speeds; receiving a request for transmission of stream data including information of a playback speed, from the receiving end; selecting a file containing stream data corresponding to the playback speed information; and transmitting the data of the selected file. Therefore, data transmission according to a desired playback speed is achieved, and the playback speed can be controlled.

According to a twelfth aspect of the present invention, there is provided a data transmission apparatus for transmitting stream data including at least one of audio and video according to a playback speed specified by a receiving end. This apparatus comprises: data storage means having, as files, plural stream data having different playback speeds; playback speed/file mapping table buffer containing a playback speed/file mapping table which indicates the correspondences between the playback speeds and the files; transmission request reception means for receiving and analyzing a request for transmission stream data from the receiving end; playback speed information extraction means for extracting information of a playback speed, from the transmission request received by the transmission request reception means; file selection means for selecting a file corresponding to the playback speed with reference to the playback speed/file mapping table stored in the playback speed/file mapping table buffer; file reading means for reading the file selected by the file selection means from the data

storage means; and transmission means for transmitting the data of the file read by the file reading means. Therefore, data transmission according to a desired playback speed is achieved, and the playback speed can be controlled.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Hereinafter, a data reception/playback apparatus and a data reception/playback method according to a first embodiment of the present invention will be described with reference to figures 1 to 7.

Figure 1 is a diagram illustrating a general file format of stream data. In figure 1, a stream data storage area 102 is

divided into plural units, and each unit contains unit header information 104 (e.g., data size information, playback time information, and the like) and stream data 105. A header information area 101 contains information such as the types of media stored in the respective units of the stream data storage area 102.

Next, a method of receiving data from some midpoint in a file using the HTTP will be described with reference to figure 2. As shown in figure 2, in a transmission request 203 by which the data reception/playback apparatus 201 requests the transmission apparatus 202 to transmit data, a transmission range 204 indicating a transmission start position is specified separately from specifying a file to be transmitted, whereby the data reception/playback apparatus can receive the data from a desired position in the file. The specified transmission start position indicates the number of bytes from the head of the file.

Usually, the size of each unit included in the stream data is variable. Therefore, when the data reception/playback apparatus performs data playback from the head of the file, it can correctly read the stream data from the file by utilizing the size information included in the unit header information attached to each unit (refer to figure 1). However, when the apparatus receives the stream data from some midpoint of the file, it cannot specify the head position of the unit and therefore cannot read the stream data correctly.

DocId: 34954560

Thereby, the data reception/playback apparatus can specify the unit head position even when it receives the data from some midpoint in the tile. Thereby, the apparatus can analyze the file format to correctly take the stream data from the file. Figure 3 shows an example of a playback start position table 301. In figure 3 playback start positions 302, 303, and 304 indicate, for example, the head positions of units constituting the stream data storage areas, and each playback start position indicates the number of bytes from the head position of the stream data storage area 102.

Figure 4 is a block diagram illustrating the data

The data reception/playback apparatus 401 comprises a control means 1801; a transmission request sending means 1803; a reception means 1806; a reception buffer 1808; a playback means 1812; a playback start position table extraction means 403 for extracting a playback start position table 404 from received data 402 stored in the reception buffer 1808; a playback start position table buffer 405 for storing the playback start position table 404; and a playback start position selection means 407 for selecting a playback start position 408 from the playback start position table 404 stored in the playback start position table buffer 405.

The control means 1801 instructs the transmission request sending means 1803 to request transmission of the playback start position table from the transmission apparatus. Then, the transmission request sending means 1803 specifies, as a transmission request 1804, a data identifier of a file of the transmission start position table, and transmits the request 1804 to the transmission apparatus.

On receipt of the transmission request 1804 from the data reception/playback apparatus 401, the transmission apparatus

The reception means 1806 of the data reception/playback apparatus 401 receives the file of the transmission start position table which is transmitted from the transmission apparatus as a transmission response 1805 to the transmission request 1804, and stores the data 1807 (playback start position table) of the transmission response 1805 in the reception buffer 1808.

When there are plural playback start positions in the playback start position table 406, the method of selecting a playback start position by the playback start position selection means 407 may be arbitrarily set. For example, the selection means 407 may select a playback start position which is nearest to the playback start position indicated by the user of the data reception/playback apparatus.

The playback start position indicated by the user or the like is not restricted to that specified by using the byte position. For example, the byte positions corresponding to the playback times at equal intervals (e.g., byte positions corresponding to the playback times 1 sec., 2 sec., 3 sec., ...) may be stored in the playback start position table, whereby the playback start position can be specified by the playback time.

Next, the control means 1801 instructs the transmission request sending means 1803 to make a request for transmission of stream data from the transmission start position 408 selected by the playback start position selection means 407. The transmission request sending means 1803 specifies a transmission range 204 as shown in figure 2 on the basis of the transmission start position specified by the control means 1801, and sends a transmission request 1804 to the transmission apparatus. The reception means 1806 receives a transmission response 1805 to the transmission request 1804, and stores it in the reception buffer 1808. The playback means 1812 plays the stream data stored in the reception buffer 1808, and outputs the played data as an output signal 1813.

As described above, according to the first embodiment, the data transmission start position from the transmission apparatus is decided on the basis of the transmission start position table which has previously been received by the data reception/playback apparatus, whereby the data reception/playback apparatus

can receive the data from the playable position such as the unit head position in the file. Therefore, even when the data reception/playback apparatus receives the stream data from some midpoint in the stream, it can correctly play the stream data, thereby realizing the jump playback function.

[Embodiment 2]

Hereinafter, a data reception/playback method and a data reception/playback apparatus according to a second embodiment of the present invention will be described.

The data reception/playback method and apparatus according to this second embodiment are different from those of the first embodiment in that the above-described playback start position table is stored in the file containing the stream data while in the first embodiment the playback start position table and the stream data are stored in different files.

Figure 5(a) shows an example of a format where a playback start position table area is placed in the vicinity of the head of a file. Although, in figure 5(a), the playback start position table area 301 containing the playback start position table follows the head information area 201 at the head of the file, the playback start position table area 301 may be placed before the header information area 201.

Hereinafter, the data reception/playback apparatus according to the second embodiment, which realizes the jump playback function, will be described.

The construction of the data reception/playback apparatus according to the second embodiment is identical to that of the data reception/playback apparatus already described for the first embodiment by using figure 4 and, therefore, does not require repeated description.

Next, the operation of the data reception/playback apparatus according to the second embodiment will be described with reference to figure 4.

The control means 1801 instructs the transmission request sending means 1803 to make a request for transmission of a file containing stream data. The transmission request sending means 1803 specifies, as a transmission request 1804, the data identifier of the file containing the stream data specified by the control means 1801, and sends the request 1804 to the transmission apparatus.

On receipt of the transmission request 1804 from the data reception/playback apparatus 401, the transmission apparatus analyzes the transmission request 1804, and transmits the file containing the stream data corresponding to the data identifier for which the transmission request is made, to the reception/playback apparatus.

When the file containing the stream data is transmitted from the transmission apparatus as a transmission response 1805 to the transmission request 1804, the reception means 1806 of the data reception/playback apparatus 401 sequentially receives the file

and stores it in the reception buffer 1808.

The playback start position table extraction means 403 extracts the playback start position table from the playback start position table area 301 of the file shown in figure 5(a), and outputs it to the playback start position table buffer 405. Since the playback start position table area 301 is placed in the vicinity of the head of the file, the playback start position table can be extracted in a short time from the start of data reception.

After the playback start position table extraction means 403 extracts the playback start position table 404, the control means 1801 of the data reception/playback apparatus 401 decides whether the data is to be played from the head of the file or from some midpoint in the file. When the data is to be played from the head of the file, the stream data storage area is subsequently received and played. When the data is to be played from some midpoint in the file, data reception is halted temporarily, and data playback is performed from the playback start position 408 selected from the playback start position table by the playback start position selection means 407.

As described above, the playback start position table stored in the file is extracted in advance of data playback, and when the data is to be played from some midpoint in the file, data reception is suspended to decide the data transmission start position from the transmission apparatus on the basis of the

extracted playback start position table. Thereby, the data reception/playback apparatus can correctly play the stream data even when it receives the data from some midpoint in the stream data, realizing the jump playback function.

While in this second embodiment the playback start position table is stored in the vicinity of the head of a file, the table may be stored so as to occupy a fixed-size area from the end of the file.

Figure 5(b) shows an example of a format where a playback start position table 301 is stored at the end of a file. According to the transmission range specification by the HTTP, the transmission range can also be specified from the end of a file. When the playback start position table is stored so as to occupy a fixed-size area from the end of the file, the data reception/playback apparatus can receive the playback start position table stored at the end of the file, in advance of data reception. The transmission range specification from the end of the file by the HTTP is performed by setting the transmission range at a minus value. For example, when -1000 is specified as the transmission range, 1000 bytes of data from the end of the file are transmitted to the data reception/playback apparatus.

Hereinafter, a description will be given of the operation of the data reception/playback apparatus in the case where the playback start position table is stored so as to occupy a fixed-size area from the end of a file, with reference to figure 4.

This is realized by storing the playback start position table so as to occupy a fixed-size area from the end of the file, whereby the data reception/playback apparatus can receive only the area of the playback start position table in advance of data reception.

The transmission request sending means 1803 specifies, as a transmission request 1804, the data identifier of the file containing the stream data specified by the control means 1801, and the size of the playback start position table area from the end of the file (transmission range specification), and sends the transmission request 1804 to the transmission apparatus.

On receipt of the transmission request 1804 from the data reception/playback apparatus 401, the transmission apparatus analyzes the transmission request 1804, and transmits a transmission-range-specified transmission start position table included in the file corresponding to the data identifier specified by the transmission request 1804, to the data reception/playback apparatus.

When the transmission start position table as a transmission response 1805 from the transmission apparatus is input to the

data reception/playback apparatus 401, the reception means 1806 receives the transmission start position table and stores it in the reception buffer 1808. The playback start position table extraction means 403 takes the playback start position table from the buffer 1808, and outputs it to the playback start position table buffer 405.

After the playback start position table extraction means 403 extracts the playback start position table 404, the control means 1801 of the data reception/playback apparatus 401 decides whether the data is to be played from the head of the file or from some midpoint in the file. When the data is to be played from the head of the file, the stream data storage area is subsequently received and played. When the data is to be played from some midpoint in the file, data reception is halted temporarily, and data playback is performed from the playback start position 408 selected from the playback start position table by the playback start position selection means 407.

As described above, even when the transmission start position table is stored so as to occupy a fixed-size area from the end of the file, since the transmission range from the end of the file is specified, the reception/playback apparatus 401 can receive the transmission start position table in advance of data reception. Therefore, even when the data reception/playback apparatus receives the stream data from some midpoint in the stream, it can correctly play the stream data, thereby realizing

Furthermore, information indicating the position of the playback start position table in the file may be stored in the vicinity of the head of the file, and the playback start position table stored in the file may be extracted according to this positional information.

As shown in figure 6, information 601 indicating the position of the playback start position table is stored in the file.

Figure 7 is a block diagram illustrating a data

The data reception/playback apparatus 701 comprises a control means 1801; a transmission request sending means 1803; a reception means 1806; a reception buffer 1808; a playback means 1812; a playback start position table extraction means 403; a playback start position table buffer 405; a playback start position table selection means 407; and a playback start position table position information extraction means 703 for extracting information indicating the position of a playback start position table in a file.

The transmission apparatus transmits the requested file to the reception/playback apparatus, on the basis of the transmission request 1804.

When the file corresponding to the transmission request 1804 is transmitted from the transmission apparatus, the reception means 1806 of the data reception/playback apparatus 701 receives a transmission response 1805 to the transmission request 1804 and stores it in the reception buffer 1808.

The playback start position table position information extraction means 703 extracts the information about the position of the playback start position table, and outputs it to the control means 1801.

On receipt of the positional information, the control means 1801 decides whether the data is to be played from the head of the file or from some midpoint in the file. When the data is to be played from the head of the file, the following stream data storage area is received and played.

On the other hand, when the data is to be played from some midpoint in the file, data reception is temporarily halted, and the control means 1801 notifies the transmission request sending means 1803 of the position of the playback start position table which is indicated by the positional information 704 extracted by the positional information extraction means 703, and the transmission request sending means 1803 sends the positional information 704 as a file transmission request 1804 to the transmission apparatus.

On receipt of the transmission request 1804, the transmission apparatus transmits file data (playback start

position table) in the position indicated by the transmission request 1804, to the data reception/playback apparatus 701.

The reception means 1806 of the data reception/playback apparatus 701 receives the playback start position table as a transmission response 1805 to the transmission request 1804, and stores it in the reception buffer 1808. The playback start position table extraction means 403 extracts the playback start position table 404 from the buffer 1808, and outputs it to the playback start position table buffer 405.

After the playback start position table extraction means 403 extracts the playback start position table 404 from the buffer 405, the control means 1801 decides whether the data is to be played from the head of the file or from some midpoint in the file. When the data is to be played from the head of the file, the stream data storage area is subsequently received and played. When the data is to be played from some midpoint in the file, data reception is temporarily halted, and data playback is performed from the playback start position 408 selected from the playback start position table by the playback start position selection means 407.

As described above, since the information about the position of the playback start position table is stored in the vicinity of the head of the file, the data reception/playback apparatus can extract the playback start position table stored in the file, and obtain the transmission start position table in advance of data

reception. Therefore, even when the data reception/playback apparatus receives the stream data from some midpoint in the stream, it can correctly play the stream data, thereby realizing the jump playback function.

In the first and second embodiments, the head position of each unit in a file format is used as an example of a playback start position. However, the playback start position depends on the stream data coding method. When data playback can be started only from the head unit of an intra-frame coded file, only the head unit of the intra-frame coded file may be used as a playback start position.

Further, in the first and second embodiments, a request for transmission of the playback start position table is made before starting data playback. However, once received playback start position table may be stored, and this table may be used for data playback when starting second or later playback for the same data, without making a request for the table.

Furthermore, in the first and second embodiments, the data reception/playback apparatus obtains the playback start position table from the file every time before starting data playback. However, since the apparatus does not need the playback start position table when playing the data from the head of the file, it may obtain the table only when performing jump playback.

Furthermore, in the second embodiment, the data reception/playback apparatus obtains the information about the

000227-84966750

Moreover, although, in the first and second embodiments, the data reception/playback apparatus makes a request for transmission of the whole playback start position table stored in the transmission apparatus, it may make a request for transmission of part of the playback start position table stored in the transmission apparatus.

[Embodiment 3]

The data reception/playback apparatus and method according to the third embodiment are applicable to data transmission using a transmission protocol such as the HTTP, wherein transmission of

Figure 8 is a block diagram illustrating a data reception/playback apparatus 801 according to the third embodiment. In figure 8, the same reference numerals as those described for the conventional apparatus shown in figure 18 denote the same components and signals.

The data reception/playback apparatus 401 so constructed operates as follows.

Hereinafter, the method of halting data reception will be described. The HTTP employs TCP (Transport Control Protocol) as a lower protocol. So long as the HTTP receives no data from the

The following process is performed to restart data playback. That is, the reception halt/restart instruction means 802 instructs the reception means 1806 to restart data reception, and the control means 1801 instructs the playback means 1812 to perform data playback.

As another method for halting and restarting data playback, the data reception/playback method described for the first or second embodiment may be employed. To be specific, the data reception/playback apparatus stores the byte position of the stream data, which has been received, when halting data playback, and thereafter, disconnects the HTTP. When restarting playback, the apparatus connects the HTTP, and specifies a transmission range by the data reception/playback method described for the first or second embodiment on the basis of the stored byte position, and requests the transmission apparatus to transmit

stream data.

Thereby, temporary halt and restart of data playback are achieved in the data reception/playback apparatus.

[Embodiment 4]

Hereinafter, a data reception/playback apparatus and a data reception/playback method according to a fourth embodiment of the present invention will be described with reference to figure 12.

The data reception/playback apparatus and method according to the fourth embodiment avoid degradation of image quality and overflow of the reception buffer even when transmission delay occurs due to network congestion when plural stream data are simultaneously received and played.

Figure 12 is a block diagram illustrating the data reception/playback apparatus according to the fourth embodiment. In figure 12, the same reference numerals as those described for the conventional data reception/playback apparatus shown in figure 18 denote the same components and signals. Reference numerals with following "a" or "b" correspond to the same reference numerals without "a" or "b" shown in figure 18.

The data reception/playback apparatus 1201 comprises a control means 1801, a transmission request sending means 1803a and 1803b, reception means 1806a and 1806b, reception buffers 1808a and 1808b, playback means 1812a and 1812b, and reception buffer monitor means 1202a and 1202b for monitoring the quantity of data being stored in the reception buffers 1808a and 1808b.

Figure 13 is a flowchart for explaining the operation of the

data reception/playback apparatus according to the fourth embodiment. When either the reception buffer 1808a or 1808b becomes empty, playback of all stream data is halted (S1301). Next, a request for halting data transmission is sent to the transmission apparatus, with respect to the connections which receives the stream data other than the stream data corresponding to the reception buffer which has become empty (S1302).

As a method for halting and restarting data reception, the method described for the third embodiment may be used. That is, data playback is halted until a predetermined quantity of data is stored in the reception buffer which has become empty (S1303). When a predetermined quantity of data is stored in the reception buffer, data playback for all streams is restarted (S1304).

Figure 14 is a graph illustrating the quantity of data stored in the reception buffer according to the above-described operation flow.

At time T1 (1403), the buffer for stream 1 (1401) becomes empty. At this time, playback of all streams is halted. At time T4 (1404), the quantity of data of stream 1 (1401) exceeds a predetermined value and, therefore, playback of all streams is restarted.

As described above, when plural stream data are simultaneously received for synchronous playback, if the quantity of data in a first reception buffer becomes zero, playback of all stream data is halted, and transmission of stream data other than

While in this fourth embodiment two pieces of stream data are processed, the above-mentioned method is applicable to processing three or more pieces of stream data.

Furthermore, the data transmission protocol according to this fourth embodiment is not restricted to the HTTP. Any other protocol may be used so long as it can control transmission of plural stream data independently. For example, RTSP (Real Time Streaming Protocol) or RTP (Realtime Transport Protocol) may be used.

Hereinafter, a data transmission apparatus and a data transmission method according to a fifth embodiment of the present invention will be described with reference to figures 15

In this fifth embodiment, the data transmission apparatus stores plural pieces of stream data having different playback speeds, and stream data to be transmitted is switched according to a playback speed requested by a data reception/ playback apparatus.

The data transmission apparatus 1501 comprises a transmission request reception means 1902; a playback speed information extraction means 1502 for extracting playback speed information from a transmission request received by the request reception means 1902; a file selection means for selecting a file corresponding to the requested playback speed, according to the playback speed information extracted by the extraction means 1502, the data identifier (URI) corresponding to the file, and a playback-speed/file mapping table; a playback-speed/file mapping table buffer 1505 for storing the playback-speed/file mapping table; a data storage means 1907 for storing plural files corresponding to the playback speeds; a file reading means 1906; and a transmission means 1909.

The data transmission apparatus 1501 so constructed operates

The transmission request reception means 1902 receives the transmission request 1901 from the data reception/playback apparatus, and sends it to the playback speed information extraction means 1502. The extraction means 1502 extracts the playback speed information and the data identifier of the requested data from the transmission request 1902, and informs them to the file selection means 1504.

Figure 16 shows an example of a playback-speed/file mapping table, wherein 1601 is a column showing playback speeds, and 1602 is a column showing file names corresponding to the playback speeds. For example, when "1.0" is specified as a playback speed from the data reception/playback apparatus, the file selection means 1504 selects a file name "stream.mpg" corresponding to the playback speed "1.0" on the basis of the playback-speed/file mapping table. The file selection means 1504 sends the selection file information 1905 to the file reading means 1906.

As described above, since the transmission apparatus holds the playback-speed/file mapping table and transmits file data corresponding to a transmission speed requested by the data reception/playback apparatus, data transmission according to the playback speed is achieved, and the playback speed can be controlled.

The playback-speed/file mapping table may be transmitted from the data transmission apparatus to the data reception/playback apparatus in advance of data transmission, or the data reception/playback apparatus may be provided with the mapping table. In this case, the data reception/playback apparatus selects a file to be requested for transmission, and conducts a transmission request for the selected file.

Furthermore, the data transmission protocol used in this fifth embodiment is not restricted to the HTTP, and other protocols may be used.
